

MIE 1622H: Assignment 2 – Risk-Based and Robust Portfolio Selection Strategies

Dr. Oleksandr Romanko

February 11, 2019

Due: Tuesday, March 5, 2019, not later than 6:00 p.m.

Use MATLAB or Python for all MIE 1622H assignments.

You should hand in:

- Your report.
- Compress all of your MATLAB or Python code files and output files into a file **StudentID.zip** (which can be uncompressed by 7-zip (<http://www.7-zip.org>) software under Windows), and submit it via Quercus portal no later than 6:00 p.m. on March 5.

Where to hand in: Online via Quercus portal, both your code and report.

Introduction

The purpose of this assignment is to compare computational investment strategies based on selecting portfolio with equal risk contributions and using robust mean-variance optimization. In Assignment 1, you have already implemented and compared computational investment strategies based on minimizing portfolio variance, maximizing Sharpe ratio as well as “equally weighted” and “buy and hold” portfolio strategies.

You are proposed to test seven strategies (use your implementation of strategies 1-4 from Assignment 1):

1. “Buy and hold” strategy;
2. “Equally weighted” (also known as “ $1/n$ ”) portfolio strategy;
3. “Minimum variance” portfolio strategy;
4. “Maximum Sharpe ratio” portfolio strategy;
5. “Equal risk contributions” portfolio strategy;
6. “Leveraged equal risk contributions” portfolio strategy;
7. “Robust mean-variance optimization” portfolio strategy.

If a portfolio strategy relies on some targets, e.g., target return estimation error, you need to select those targets consistently for each holding period. It is up to you to decide how to select those targets.

Feel free to use MATLAB prototypes provided in class.

Questions

1. (70 %) Implement investment strategies in MATLAB:

You need to test three portfolio re-balancing strategies:

1. “Equal risk contributions” portfolio strategy: compute a portfolio that has equal risk contributions to standard deviation for each period and re-balance accordingly. You can use IPOPT example from the lecture notes, but you need to compute the gradient of the objective function yourself (to validate your gradient computations you may use finite differences method). The strategy should be implemented in the function `strat_equal_risk_contr`.
2. “Leveraged equal risk contributions” portfolio strategy: take long 200% position in equal risk contributions portfolio and short risk-free asset for each period and re-balance accordingly, implement it in the function `strat_lever_equal_risk_contr`. You do not have to include risk-free asset as an additional asset when calculating optimal positions. Just make sure that you subtract amount borrowed when calculating portfolio value in a similar way as you do for transaction cost at each time period.
3. “Robust mean-variance optimization” portfolio strategy: compute a robust mean-variance portfolio for each period and re-balance accordingly. You can use CPLEX example from the lecture notes, but you need to select target risk estimation error and target return according to your preferences as an investor (provide justification of your choices). The strategy should be implemented in the function `strat_robust_optim`.

Design and implement a rounding procedure, so that you always trade (buy or sell) an integer number of shares.

Design and implement a validation procedure in your code to test that each of your strategies is feasible (you have enough budget to re-balance portfolio, you correctly compute transaction costs, funds in your cash account are non-negative).

There is a file `portf_optim2.m` on the course web-page. You are required to complete the code in the file.

Your MATLAB code should use only CPLEX and IPOPT optimization solvers.

2. (15 %) Analyze your results:

- Produce the following output for the 12 periods (years 2015 and 2016):

```
Period 1: start date 1/2/2015, end date 2/27/2015
Strategy "Buy and Hold", value begin = $ 1000002.12, value end = $ 1043785.08
Strategy "Equally Weighted Portfolio", value begin = ... , value end = ...
Strategy "Minimum Variance Portfolio", value begin = ... , value end = ...
Strategy "Maximum Sharpe Ratio Portfolio", value begin = ... , value end = ...
Strategy "Equal Risk Contributions Portfolio", value begin = ... , value end = ...
Strategy "Leveraged Equal Risk Contributions Portfolio", value begin = ... , value end = ...
Strategy "Robust Optimization Portfolio", value begin = ... , value end = ...

...

Period 12: start date 11/1/2016, end date 12/30/2016
Strategy "Buy and Hold", value begin = $ 1077523.53, value end = $ 1173675.24
Strategy "Equally Weighted Portfolio", value begin = ... , value end = ...
```

```

Strategy "Minimum Variance Portfolio", value begin = ..., value end = ...
Strategy "Maximum Sharpe Ratio Portfolio", value begin = ..., value end = ...
Strategy "Equal Risk Contributions Portfolio", value begin = ..., value end = ...
Strategy "Leveraged Equal Risk Contributions Portfolio", value begin = ... , value end = ...
Strategy "Robust Optimization Portfolio", value begin = ..., value end = ...

```

- Plot one chart in MATLAB that illustrates the daily value of your portfolio (for each of the seven trading trading strategies) over the years 2015 and 2016 using daily prices provided. Include the chart in your report.
- Plot one chart in MATLAB to show dynamic changes in portfolio allocations under strategy 7. In each chart, x -axis represents the rolling up time horizon, y -axis denotes portfolio weights between 0 and 1, and distinct lines display the position of selected assets over time periods. Does your robust portfolio selection strategy reduce trading as compared with strategies 3 and 4 that you have implemented in Assignment 1?
- Compare your “equal risk contributions”, “leveraged equal risk contributions” and “robust mean-variance optimization” trading strategies between each other and to four strategies implemented in Assignment 1 and discuss their performance relative to each other. Which strategy would you select for managing your own portfolio and why?

3. (15 %) Test your trading strategies for years 2008 and 2009:

- Download daily closing prices for the same twenty stocks for years 2008 and 2009 (file **MIE1622H_Assign2_data_2008-2009.zip**). If necessary, transform data into a format that your code can read.
- Test seven strategies that you have implemented for the 12 periods (years 2008 and 2009). Use the same initial portfolio that you are given in Assignment 1. Produce the same output for your strategies as in Question 2.
- Plot one chart in MATLAB that illustrates the daily value of your portfolio (for each of the six trading strategies) over the years 2008 and 2009 using daily prices that you have downloaded. Include the chart in your report.
- Plot three charts in MATLAB for strategies 3, 4 and 7 to show dynamic changes in portfolio allocations using the new data set. Does your robust portfolio selection strategy reduce trading as compared with the strategies 3 and 4?
- Compare and discuss relative performance of your seven trading strategies during 2015-2016 and 2008-2009 time periods. Which strategy would you select for managing your own portfolio during 2008-2009 time period and why?

MATLAB Script to be Completed

```

clc;
clear all;
format long

% Input files
input_file_prices = 'Daily_closing_prices.csv';

% Read daily prices
if(exist(input_file_prices,'file'))
    fprintf('\nReading daily prices datafile - %s\n', input_file_prices)
    fid = fopen(input_file_prices);

```

```

    % Read instrument tickers
    hheader = textscan(fid, '%s', 1, 'delimiter', '\n');
    headers = textscan(char(hheader{:}), '%q', 'delimiter', ',');
    tickers = headers{1}(2:end);
    % Read time periods
    vheader = textscan(fid, '%[^,]*%[\n]');
    dates = vheader{1}(1:end);
    fclose(fid);
    data_prices = dlmread(input_file_prices, ',', 1, 1);
else
    error('Daily prices datafile does not exist')
end
